Dear Editor,

Bats are mammals documented to be infected by coronavirus SARS-like related to SARS-CoV-2 which cause COVID-19.⁽¹⁾ Bats represent about 20% of all classified mammal species, over 1,200 species. They are largely fruit-eating, seed dispersers and pollinators around the world,⁽²⁾ this made this species important in the ecosystems ecology.

When the COVID-19 pandemic was declared in December 2019, the search for origins was found in sequencing of coronavirus related to bats. This suggests that these animals may be long-term reservoir host for the coronavirus SARS-like betacoronaviruses and may recombine between species of bats.⁽¹⁾ The species of bats related to the coronavirus SARS-like are *Rhinolophus affinis* and *Rhinolophus sinicus* and are distributed principally in China, Europe and Africa (Fig. 1).⁽³⁾ The sequences of new coronavirus has been submitted to [GISaid](#) and [GenBank](#). The most emparented coronavirus SARS-like is BetaCoV/bat/Yunnan/RaTG13/2013 found in *Rhinolophus affinis* with 96.2% (accession MN996532) similarity with WH-Human_1 (SARS-CoV-2) (accession MN908947) (Fig. 2) the first sequencing sample in humans, although the SARS-CoV-2 was closer to the bat_SL_CoVZC45 (accession MG772933) and the bat_SL_CoVZXC21 (accession MG772934) both found in *Rhinolophus sinicus*.⁽³⁾ The genus *Rhinolophus* (horseshoe bats) in the family Rhinolophidae demonstrated a high possibility to be the host of SARS-like betacoronaviruses⁽⁴⁾ and could cause a future disease outbreak. We have to focus on possible mutations and hosts that may cause pandemics in the future and their zoonotic role.
